On to other shores

Epilogue

One counts the number of occurrences of a given pattern  $H$  in a text of size  $n$ . This number is denoted  $O_n(H)$ .

Frequency analysis relies on the decomposition of the text  $T$  onto languages, the so-called initial, minimal, and tail languages.

Going from there to their generating functions both for a Markovian and a Bernoulli environment, it turns out the whole counting problem only depends on  $P(H)$  and the "correlation set".

# Markov sequence

## Preliminaries

Main findings I

On to other shores

Epilogue

A sequence  $X_1, X_2, \dots$  of random variates is called a *Markov sequence* of order 1 iff, for any  $n$ ,

$$F(X_n | X_{n-1}, X_{n-2}, \dots, X_1) = F(X_n | X_{n-1})$$

i.e., if the conditional distribution  $F$  of  $X_n$ , assuming  $X_{n-1}, X_{n-2}, \dots, X_1$

equals

the conditional distribution  $F$  of  $X_n$  assuming only  $X_{n-1}$ .

# Markov chain

Main findings I

On to other shores

Epilogue

If a Markov sequence of random variates  $X_n$  take the *discrete values*  $a_1, \dots, a_N$  then

$$P(x_n = a_{i_n} | x_{n-1} = a_{i_{n-1}}, \dots, x_1 = a_{i_1}) = P(x_n = a_{i_n} | x_{n-1} = a_{i_{n-1}})$$

and the sequence  $x_n$  is called a *Markov chain* of order 1.

# Correlation of patterns

Main findings I

On to other shores

Epilogue

A *correlation* of two patterns  $X$  (size  $m$ ) and  $Y$  is a string, denoted by  $XY$ , over the set  $\Omega = \{0, 1\}$ .

$$|XY| = |X|$$

Each position  $i$  can be computed as

$i = 1 \Leftrightarrow$  place  $Y$  at  $X_i \wedge$  all overlapping pairs are identical  
else  $i = 0$

# Example of pattern correlation

Let  $\Omega = \{M, P\}$ ,  $X = MPMPPM$  and  $Y = MPPMP$ .  
Then  $XY$  can be deduced in the following manner:

X:	HTHTTH	
Y:	HTTHT	0
	HTTHT	0
	HTTHT	1
	HTTHT	0
	HTTHT	0
	HTTHT	1

whilst  $YX$  can be shown to equal 00010

## Preliminaries

### Declaring languages

### Language relationships

### Languages & GFs

### Looking for GFs

### Main findings I

### On to other shores

### Epilogue

Furthermore, *autocorrelation* of  $X$  can be defined as  $XX$ .

It represents the periods of  $X$ , i.e. those shifts of  $X$  that cause that pattern to overlap itself.

Using  $Y = MPPMP$  from our previous example,  $YY$  evaluates to 10010

Using  $A = MMM$ ,  $AA$  evaluates to 111

# Autocorrelation set

Given a string  $H$ , the autocorrelation set  $A_{HH}$  or just  $A$  is defined as

$$A_{HH} = \{H_{k+1}^m : H_1^k = H_{m-k+1}^m\}$$

Epilogue

A *Bernoulli Source*, or *memoryless source*, generates text randomly.

Every subsequent symbol (of a finite alphabet) is created independently of its predecessors, and the probability of each symbol is not necessarily the same.

If it is, the Source is called a *symmetric*, or *unbiased Bernoulli Source*.

If text over an alphabet  $S$  is generated by a Bernoulli Source, then each symbol  $s \in S$  *always* occurs with probability  $P(s)$ .

Main findings I

On to other shores

Epilogue

A *Markovian Source* generates symbols based not on the *a priori* probability of each symbol.

Instead, it only needs a (finite) set of predecessors to ascertain the probability of each next symbol.

In order to do so, it requires a *memory* of previously emitted symbols.

Epilogue

Text generated by a Markovian Source is a realization of a Markov sequence of order  $K$ .

$K$  denotes the number of previous symbols that the probability of the next symbol depends on.

In our application, this sequence will be stationary and  $K = 1$ , i.e. a first-order Markov sequence.

When computing the next symbol, we only need to observe the last symbol.

Epilogue

In our case ( $K = 1$ ), the transition matrix is defined by

$$P = \{p_{i,j}\}_{i,j \in S}$$

where

$$p_{i,j} = \text{Probability } (t_{k+1} = j | t_k = i)$$

The matrix entry  $(i, j)$  denotes the conditional probability of the next symbol being  $j$  if the current symbol is  $i$ .

Epilogue

A language  $L$  is a collection of words.

This collection must satisfy certain properties to belong to a specific language.

Thus, we can associate with a language  $L$  its generating function  $L(z)$ .

# Generating functions

Given a sequence  $\{a_n\}_{n \geq 0}$ , we know its generating function is defined as

$$A(z) = \sum_{n \geq 0} a_n z^n$$

Preliminaries

Sources

GF of languages

Declaring languages

Language relationships

Languages & GFs

Looking for GFs

Main findings I

On to other shores

Epilogue

# Generating functions, too

For sinister purposes, we represent it differently as

$$A(z) = \sum_{\alpha \in S} z^{w(\alpha)}$$

where  $S$  is a set of objects (words ...) and  $w(\alpha)$  is a weight function.

Henceforth we will interpret it as the size of  $\alpha$ , i.e.  $w(\alpha) = |\alpha|$

The equivalence becomes evident when we set  $a_n$  to be the number of objects  $\alpha$  satisfying  $w(\alpha) = n$ .

Now we have a more combinatorial view

Preliminaries

Sources

# Generating function of a language

Preliminaries

Sources

GF of languages

- What is a language
- Generating functions
- Generating functions, too
- GF of a language
- Conditional GF
- Example: GF
- Formulating our objective

Declaring languages

Language relationships

Languages & GFs

Looking for GFs

Main findings I

On to other shores

Epilogue

Now, for any language  $L$ , we define its generating function  $L(z)$  as

$$L(z) = \sum_{w \in L} P(w)z^{|w|}$$

where  $P(w)$  is the probability of word  $w$ 's occurrence and  $|w|$  is the length of  $w$ .

So the coefficient of  $z^{|w|}$  is the sum of the probabilities all words of that length.

In addition, we assume that  $P(\epsilon) = 1$ . So every language includes the empty word (as we know).

# Conditional generating function

Preliminaries

Sources

GF of languages

- What is a language
- Generating functions
- Generating functions, too
- GF of a language
- Conditional GF
- Example: GF
- Formulating our objective

Declaring languages

Language relationships

Languages & GFs

Looking for GFs

Main findings I

On to other shores

Epilogue

In addition, the  $H$ -conditional generating function of  $L$  is given as

$$\begin{aligned} L_H(z) &= \sum_{w \in L} P(w | w_{-m} = h_1 \dots w_{-1} = h_m) z^{|w|} \\ &= \sum_{w \in L} P(w | w_{-m}^{-1} = H) z^{|w|} \end{aligned}$$

where  $w_{-i}$  is the symbol preceding the first character of  $w$  at distance  $i$ .

We use this definition for Markovian sources, where the probability depends on the previous symbols.

# Example: autocorrelation generating function

In our previous example, the autocorrelation set was

$$A = \{\epsilon, 01\}$$

The generating function of the set is

$$A(z) = 1 + \frac{z^2}{4}$$

given a Bernoulli source, and

$$A_{SOS}(z) = 1 + p_{SOP}p_{OS}z^2$$

given a Markovian source of order one.

Epilogue

# Formulating our objective

We will now formulate the special generating functions whose closed form we will later strive to compute:

$$1. T^{(r)}(z) = \sum_{n \geq 0} Pr(O_n(H) = r) z^n$$

$$2. T(z, u) = \sum_{r=1}^{\infty} T^{(r)}(z) u^r$$

$$= \sum_{r=1}^{\infty} \sum_{n=0}^{\infty} Pr(O_n(H) = r) z^n u^r$$

Epilogue

# Composition proof ( $T_r$ )

Proof: First occurrence of  $H$  in a  $T_r$  word determines the prefix

$p$

which is in  $R$ .

From that prefix on, we look onward until the next occurrence of  $H$ .

The found word  $w$  is  $\in M$ .

After  $r - 1$  iterations, we add a  $H$ -devoid suffix, which is in  $U$ , because its prefix has  $H$  at the end.

Epilogue

# Four more relationships I (2)

→:

Let  $w \in \bigcup_{k \geq 1} M^k$ .

Iff  $|w| \geq |H|$ , then surely the inclusion is correct.

Iff  $|w| < |H|$  (how can that be?), then  $w \notin W \cdot H$ .

But then, necessarily,  $w \in A - \{\epsilon\}$ , because the second  $H$  in  $Hw$  overlaps with the first  $H$  by definition (it is element of  $M^k$ ), so  $w$  must be in the autocorrelation set  $A$ .

Proof:

All words of  $S$  consist of a single character  $s$ .

Given a word  $u \in U$  and concatenating them, we differentiate two cases.

If  $Hus$  contains a second occurrence of  $H$ , it is clearly at the right end. Then  $us \in M$ .

If  $Hus$  does contain only a single  $H$ , then  $us$  must be non-empty word of  $U$ .

Epilogue

# Four more relationships II

$$H \cdot M = S \cdot R - (R - H)$$

Proof:

→:

Let  $sw$  be a word in  $H \cdot M$ ,  $s \in S$  (we can write every such word in this way WLOG).

$sw$  contains exactly two times  $H$ , evidently at its left, and also at its right end.

Thus,  $sw$  is also  $\in S \cdot R$

←:

If a word  $swH$  from  $S \cdot R$  is not in  $R$ , then because it contains a second  $H$  starting at the left end of  $sw$ , because  $wH \in R$ .

Of course, in that case it is  $\in H \cdot M$ .

# Four more relationships IV

$$T_0 \cdot H = R \cdot A$$

Proof:

Let  $wH$  be  $\in T_0 \cdot H$ . Then there can be either be one or more occurrences of  $H$  in  $wH$ , one of which is at the right end.

If there is no second one, then  $wH$  is  $\in R$  by definition of  $R$

If, however, there is a second one, then it overlaps somehow with the first one.

So we view the word until the end of the *first*  $H$ , which is in  $R$ . Due to the overlapping, the remaining part is  $\in A$ .

Epilogue

# One more

Combining relationships II and III yields

$$H \cdot U \cdot S - H \cdot U = (S - \epsilon)R$$

No proof is necessary, as we have validated both ingredients.

Using II, the left side is  $H(U \cdot S - U) = H \cdot M$

The right side is

$$\begin{aligned} S \cdot R - R \\ &= S \cdot R - (R \cap S \cdot R) \\ &= S \cdot R - (R - H) \end{aligned}$$

Together, that is just relationship III.

# What is left to do?

We still have no formula of gathering  $O_n(H)$ , i.e. the frequency of  $H$ -occurrences ( $|H| = m$ ) in random text of length  $n$  over an alphabet  $S$  with  $|S| = V$ .

Let us make an educated guess, though.

What we do not know, is how important *overlapping* is. Assuming to disregard that topic, the answer *could* be

$$E[O_n(H)] = P(H)(n - m + 1)$$

It is.

But why?

Epilogue

● Questions?

*"O, call not me to justify the wrong  
That thy unkindness lays upon my heart;  
Wound me not with thine eye but with thy tongue;  
Use power with power and slay me not by art.  
What need'st thou wound with cunning when thy might  
Is more than my o'er-press'd defense can bide?  
That they elsewhere might dart their injuries:  
Yet do not so; but since I am near slain,  
Kill me outright with looks and rid my pain."  
Shakespeare Sonnet CXXXIX*

# With what certainty (1)

the variance of  $E(O_n(H))$  is, for a  $r > 1$ :

$$\text{Var}[O_n(H)] = nc_1 + c_2 + O(r^{-n})$$

where

$$c_1 = P(H)(2A_H(1) - 1 - (2m - 1)P(H) + 2P(H)E_1))$$

$$c_2 = P(H)((m - 1)(3m - 1)P(H) - (m - 1) \\ (2A_H(1) - 1) - 2A'_H(1)) - 2(2m - 1) \\ (P(H)^2 E_1 + 2E_2 P(H)^2)$$

Epilogue

● Questions?

# Simplification

Luckily (...), for a *memoryless source*, both constants  $E$  are void, as  $P$  is then equal to  $\Pi$ .

So in that, we have

$$c_1 = P(H)(2A(1) - 1 - (2m - 1)P(H))$$

$$c_2 = P(H)((m - 1)(3m - 1)P(H) - (m - 1)(2A(1) - 1) - 2A'(1))$$
