# **Parallel Comparison Tree Model**

A parallel comparison tree (with parallelism p) is a  $3^p$ -ary tree.

- each internal node represents a set of p comparisons btw.
   p pairs (not necessarily distinct)
- ightharpoonup a leaf v corresponds to a unique permutation that is valid for all the comparisons on the path from the root to v
- the number of parallel steps is the height of the tree

# A Lower Bound for Searching

#### Theorem 1

Given a sorted table X of n elements and an element y. Searching for y in X requires  $\Omega(\frac{\log n}{\log(p+1)})$  steps in the parallel comparsion tree with parallelism p < n.

**Comparison PRAM** 

A comparison PRAM is a PRAM where we can only compare the input elements;

- we cannot view them as strings
- we cannot do calculations on them

A lower bound for the comparison tree with parallelism p directly carries over to the comparison PRAM with p processors.

## A Lower Bound for Maximum

## **Theorem 2**

A graph G with m edges and n vertices has an independent set on at least  $\frac{n^2}{2m+n}$  vertices.

base case (n = 1)

► The only graph with one vertex has m = 0, and an independent set of size 1.

induction step  $(1, \ldots, n \rightarrow n + 1)$ 

- Let G be a graph with n+1 vertices, and v a node with minimum degree (d).
- Let G' be the graph after deleting v and its adjacent vertices in G.
- n' = n (d+1)
- $m' \le m \frac{d}{2}(d+1)$  as we remove d+1 vertices, each with degree at least d
- ▶ In G' there is an independent set of size  $((n')^2/(2m'+n'))$ .
- ightharpoonup By adding v we obtain an indepent set of size

$$1 + \frac{(n')^2}{2m' + n'} \ge \frac{n^2}{2m + n}$$

An adversary can specify the input such that at the end of the (i+1)-st step the maximum lies in a set  $C_{i+1}$  of size  $s_{i+1}$  such that

- ▶ no two elements of  $C_{i+1}$  have been compared
- $> s_{i+1} \ge \frac{s_i^2}{2p + c_i}$

## A Lower Bound for Maximum

#### Theorem 3

Computing the maximum of n elements in the comparison tree requires  $\Omega(\log\log n)$  steps whenever the degree of parallelism is  $p \le n$ .

#### Theorem 4

Computing the maximum of n elements requires  $\Omega(\log \log n)$  steps on the comparison PRAM with n processors.

# **A Lower Bound for Merging**

The (k,s)-merging problem, asks to merge k pairs of subsequences  $A^1,\ldots,A^k$  and  $B^1,\ldots,B^k$  where we know that all elements in  $A^i \cup B^i$  are smaller than elements in  $A^j \cup B^j$  for (i < j).

9 Lower Bounds

160

162

# **A Lower Bound for Merging**

Partition  $A^is$  and  $B^is$  into blocks of length roughly  $s/\ell$ ; hence  $\ell$  blocks.

Define an  $\ell \times \ell$  binary matrix  $M^i$ , where  $M^i_{\chi y}$  is 0 iff the parallel step **did not** compare an element from  $A^i_\chi$  with an element from  $B^i_{\gamma}$ .

The matrix has  $2\ell - 1$  diagonals.

# A Lower Bound for Merging

#### Lemma 6

Suppose we are given a parallel comparison tree with parallelism p to solve the (k,s) merging problem. After the first step an adversary can specify the input such that an arbitrary (k',s') merging problem has to be solved, where

$$k' = \frac{3}{4} \sqrt{pk}$$

$$s' = \frac{s}{4} \sqrt{\frac{k}{p}}$$

9 Lower Bounds

161

Choose for every i the diagonal of  $M^i$  that has most zeros.

Pair all  $A^i_{j+d_i}$ ,  $B^i_j$ , (where  $d_i \in \{-(\ell-1), \ldots, \ell-1\}$  specifies the chosen diagonal) for which the entry in  $M^i$  is zero.

We can choose value s.t. elements for the j-th pair along the diagonal are **all** smaller than for the (j+1)-th pair.

Hence, we get a (k', s') problem.

## How many pairs do we have?

- there are  $k\ell$  blocks in total
- there are  $k \cdot \ell^2$  matrix entries in total
- ▶ there are at least  $k \cdot \ell^2 p$  zeros.
- $\triangleright$  choosing a random diagonal (same for every matrix  $M^i$ ) hits at least

$$\frac{k\ell^2 - p}{2\ell - 1} \ge \frac{k\ell}{2} - \frac{p}{2\ell}$$

zeroes.

► Choosing  $\ell = 2\sqrt{\frac{p}{k}}$  gives

$$k' \ge \frac{3}{4}\sqrt{pk}$$
 and  $s' = \lfloor \frac{s}{\ell} \rfloor \ge \frac{s}{2\ell} = \frac{s}{4}\sqrt{\frac{k}{p}}$ 

where we assume  $\frac{s}{\ell} \ge 2$ .

#### 164

## **Induction Step:**

Assume that

$$T(k', s', p) \ge \frac{1}{4} \log \frac{\log \frac{p}{k'}}{\log \frac{p}{k's'}}$$

$$\ge \frac{1}{4} \log \frac{\log \frac{4}{3} \sqrt{\frac{p}{k}}}{\log \frac{16}{3} \frac{p}{ks}}$$

$$\ge \frac{1}{4} \log \frac{\frac{1}{2} \log \frac{p}{k}}{7 \log \frac{p}{ks}}$$

$$\ge \frac{1}{4} \log \frac{\log \frac{p}{k}}{\log \frac{p}{ks}} - 1$$

This gives the induction step.
